

Datacenter REIT Stability and Growth

Committee summary · EQIX, DLR, IRM · trailing twelve months

Prepared by C. Davenport for S. Chen and the Investment Committee

Bottom line

Of the three data center REITs examined, Equinix was the strongest performer over the past year. It recorded the steepest price growth, followed the most consistent upward pattern and was the most stable of the three for all but the opening month. Its primary practical drawback is its share price, which is substantially higher than those of Iron Mountain and Digital Realty. Iron Mountain ranks second, having recorded slightly stronger price growth than Digital Realty while remaining the most volatile company in the group. Digital Realty ranks third, with the weakest growth but otherwise steady and contained behavior for most of the year.

What we looked at

Because the firm holds these three companies across client portfolios, and because AI infrastructure has drawn growing attention to the sector, the aim was to assess whether that exposure is concentrated in the most stable and consistently growing companies. Each company was compared on growth, defined by how much and how consistently its price increased, and on stability, defined by how consistently its daily price range behaved relative to its typical level. This summary is informational rather than a recommendation to buy or sell.

How the three compare

Company	Growth	Consistency of growth	Volatility
Equinix	Strongest	Highest	Lowest for most of the year
Iron Mountain	Second	Moderate	Highest of the three
Digital Realty	Weakest	Lowest	Low but with sharp short spikes

One observation worth flagging

All three companies followed a nearly identical price path over the year, with the same mid-period dip and subsequent recovery appearing in each at roughly the same time. This suggests that shared forces, whether developments in the data center market, movements in interest rates or broader sentiment around AI, may have influenced all three holdings simultaneously. Further research into those common drivers would therefore likely add the most value

Important caveat

These conclusions rest on simplified measures of growth and stability rather than the broader set of risk and performance metrics a professional investment analysis would use, such as beta, the Sharpe ratio, drawdown and benchmark comparisons. They describe how these stocks behaved over the period. They do not predict how they will behave in the future and should not be read as investment advice. Full methodology is available on request.
